

Collective Modes in the Loop Current Ordered Phase of Cuprates

Yan He and C.M. Varma

Department of Physics, University of California, Riverside, CA

(Dated: January 31, 2012)

Recently two branches of weakly dispersive collective modes have been discovered in under-doped cuprates by inelastic neutron scattering. Polarization analysis reveals that the modes are magnetic excitations. They are only visible for temperatures below the transition temperature to a broken symmetry phase which was discovered earlier and their intensity increases as temperature is further decreased. The broken symmetry phase itself has symmetries consistent with ordering of orbital current loops within a unit-cell without breaking translational symmetry. In order to calculate the collective modes of such a state we add quantum terms to the Ashkin-Teller (AT) model with which the classical loop current order has been described. We derive that the mean field ground state of the quantum model is a product over all unit-cells of linear combination of the four possible classical configurations of the loop current order in each unit-cell. The collective modes are calculated by using a generalized Holstein-Primakoff boson representation of orbital moment operators and lead to three branches of gapped weakly dispersive collective modes. The experimental results are consistent with the two lower energy branches; the third mode is at a higher energy than looked for by present neutron scattering experiments and might also be over-damped. Implications of the discovery of the collective modes are discussed.

I. INTRODUCTION

Thermodynamic^{1,2} as well as other properties³ in all Cuprate families with high superconducting transition temperatures change their temperature dependence below about a characteristic temperature $T^*(x)$, which depends on doping x , from those at higher temperatures. The region below $T^*(x)$, see Fig. (1) is said to mark the pseudogap region. Photoemission⁴ and Angle resolved photoemission experiments reveal⁵ an anisotropic decrease in single particle spectral weight near the chemical potential below $T^*(x)$. A popular belief³ has been that $T^*(x)$ marks a crossover to a region of reduced low energy one-particle spectral weight, as well as in multiple particle-hole spectral weights, due to one or other reason, preformed pairs⁶, resonating valence bonds⁷, stripe formation⁸ or other states of charge modulation, proximity to the Mott-AFM-insulating state⁹, etc.. Guided by the fact that a “strange-metal” region whose properties can be explained by quantum-critical fluctuations¹⁰ abuts the pseudo-gap region in the phase diagram, a broken symmetry state was sought for the region below $T^*(x)$ with $T^*(x) \rightarrow 0$ at $x \rightarrow x_c$, the quantum-critical point. An unusual class of phases^{11,12} was found to be stable in mean-field calculations of the three-band model for cuprates^{14,15}. In such phases time-reversal symmetry is broken via spontaneous generation of orbital currents in each cu-o unit-cell without altering the translational symmetry. The phase transition belongs to the class with an order parameter singularity but no divergence in the specific heat^{12,28}.

An order parameter consistent with the symmetry predicted has been discovered in four different families of cuprates through polarized neutron scattering¹⁶ or dichroic ARPES¹⁷ and may be regarded as a universal

Figure 1: The universal phase diagram of hole-doped cuprates based on properties which show characteristic changes across the boundaries shown in all the cuprates. The boundary of the pseudogap phase has not yet been determined in experiments, i.e how $T^*(x)$ line continues for lower x has not been determined.

property of the cuprates. The magnitude of the order parameter is large, estimated in $Hg1201$, with $T_c \approx 61K$ and $T^* \approx 350K$, to be about $0.4\mu_B$ per unit-cell.

More recently inelastic neutron scattering has discovered¹⁸ *two* branches of weakly dispersive collective modes for three different x in the family ($Hg1201$) for T below $T^*(x)$. (Similar modes have been also found¹⁹ in $YBa_2Cu_3O_{6.6}$.) Their onset temperature and increase of spectral weight as a function of temperature follows the temperature of the intensity of the elastic order. Such modes were also anticipated¹² and further substantiate the broken symmetry. In this paper, we describe details of the calculation of such modes as well as of another

Figure 2: The four Possible “classical” domains of the loop ordered state are shown. In the classical ordered phase, one of these configurations is found in every unit-cell.

higher energy branch of excitations which has not yet been discovered. A brief report of this work has already been published²⁰.

The observed broken symmetry is consistent with spontaneous moments due to a pair of orbital current loops within each unit-cell preserving overall translational symmetry. It breaks both time-reversal and inversion symmetry, preserving their product. The “classical” order parameter²¹ may be characterized by the *anapole* vector²² $\mathbf{L}$

$$\mathbf{L} = \int_{cell} d^2r (\mathbf{M}(\mathbf{r}) \times \hat{\mathbf{r}}) \approx \sum_{\mu} \mathbf{M}_{\mu} \times \mathbf{r}_{\mu} \quad (1)$$

where the moment distribution $\mathbf{M}(\mathbf{r})$ is formed due to the currents on the four O-Cu-O triangles per unit-cell as shown in Fig. (2). This figure also shows the four possible “classical” domains of the loop current ordered state. In the classical ground state, ordering occurs in one of the domains shown.

Quantum-mechanics allows local fluctuations among the four configurations in Fig (2). This leads, as shown in this paper to a ground state in which each unit-cell has a finite admixture of all the four configurations. It also leads to three branches of collective modes of the order parameter at finite energies at all momenta $\mathbf{q}$ for $T < T^*$. The finite energy follows from the fact that the ground state has symmetry consistent with that of a generalized (transverse-field) Ising model. In this paper these modes will be derived. One can argue that there should be three because each of the four configurations can make transitions to the other three as pictorially shown in Fig. (3).

This paper is organized as follows: In the next section, we introduce the classical AT model for the loop current order and generalize it to the quantum model in the $SU(4)$ representation rather than the $SU(2) \times SU(2)$ of the classical AT model. The quantum terms are chosen from considerations of the internal and lattice symmetries of the classical model. In the following section, the ground state of the quantum model is evaluated in mean-field and the dispersion is calculated using the generalization of the Holstein-Primakoff transformation. We

Figure 3: The schematic figure shows that there are only 3 collective modes.

compare with the results from experiments. We conclude by discussing the significance of the experimental discovery of the collective modes and the further possible effects which arise from the calculations here. In four Appendices, we discuss the necessity for casting the problem in the $SU(4)$ representation, some technical details, and the theory for inelastic neutron scattering from the collective modes.

II. MODEL FOR QUANTUM-STATISTICAL MECHANICS OF LOOP-CURRENTS

The order parameter $\mathbf{L}$ and an effective Hamiltonian for this collective variable has been derived^{11,12,23} start-

ing from a model of interacting fermions¹⁴. The full Hamiltonian may be written as a sum of three parts:

$$H = H_{coll} + H_F + H_{F-coll}, \quad (2)$$

where H_{coll} is the Hamiltonian for the collective coordinates $\mathbf{L}_i$, which order at T^* to give the long range order $\mathbf{L}$, H_F is the remnant fermion Hamiltonian and H_{F-coll} is the residual interaction between the fermions and the collective coordinates. In this paper we will be concerned almost exclusively with H_{coll} , although in a brief discussion of damping near the end, H_{F-coll} is implicated.

An approximate representation of $\mathbf{L}$ of Eq. (1) is given by $\mathbf{M}(\mathbf{r}) \approx \mathbf{M}_\mu \delta^2(\mathbf{r} - \mathbf{r}_\mu)$, where $\mathbf{r}_\mu$, $\mu = 1, \dots, 4$ are the location of the four "sites" in any cell at the centroid of the moment distribution. These sites are labeled $S_1, \dots, S_4$ in Fig.(4). The orbital moments $\mathbf{M}_\mu$ are either up or down or zero. The four *classical* domains of Fig.(2) may be represented by the four values of the angle $\theta = \pi/4, 3\pi/4, 5\pi/4, 7\pi/4$ that $\mathbf{L}$ makes with the $\hat{x}$ -axis. The 4 classical loop current states are eigenvalues of operators $\mathbf{L}_i = (L_{i,x}, L_{i,y})$ defined at the unit-cell i . We may define a basis, choosing $|\mathbf{L}_i|$ to be unity,

$$(L_{i,x} + iL_{i,y})|\theta\rangle_i = e^{i\theta}|\theta\rangle_i \quad (3)$$

The classical statistical mechanics of the Loop-Current state may be derived from the Ashkin-Teller model, which is given in terms of a pair of Ising spin per unit-cell σ_i^z, τ_i^z , whose eigenvalues, ± 1 specify the x and y components of the direction of the vector $\mathbf{L}$. The four loop current states can therefore also be denoted as $|\pm 1, \pm 1\rangle$. The classical Ashkin-Teller model²⁴ is given by²⁵,

$$H_{AT} = - \sum_{\langle i,j \rangle} [J_1 \sigma_i^z \sigma_j^z + J_2 \tau_i^z \tau_j^z + J_4 \sigma_i^z \sigma_j^z \tau_i^z \tau_j^z] \quad (4)$$

Quantum fluctuations among the four possible directions of order together with dissipation lead²⁶ to a scale invariant spectrum which leads to the observed Marginal Fermi-liquid properties in the quantum-critical regime in the phase diagram, Fig. (1). In this paper, we will derive the effect of the quantum fluctuation in the ordered loop current phase. In this phase, the kinetic energy locally flips a loop current state in cell i to one of the other three states, just as the transverse field does between the two states of the transverse field Ising model. Due to this term, the ground state is a superposition, in each unit-cell, of all the 4 possible directions of $\mathbf{L}_i$. The excitations consist of local flips between the configurations which spread out spatially through interactions between neighboring sites and acquire dispersion just like spin waves in the transverse-field Ising model.

A. Symmetries

As explained in Appendix B, in order to treat the four states on the same footing in the quantum-mechanical

Figure 4: We represent here the notation introduced in the text for the location of the moments within a unit-cell.

model, we must enlarge the representation from that of 2 by 2 matrix space to that of 4 by 4 matrices, i.e. we must consider the problem in the $SU(4)$ representation rather than in the $SU(2) \times SU(2)$ representation. We introduce the following direct products between Pauli matrices.

$$S^i = \sigma^i \otimes I, \quad T^i = I \otimes \tau^i, \quad K^{ij} = \sigma^i \otimes \tau^j \quad (5)$$

The 15 traceless matrices S , T and K are also the generators of $SU(4)$ algebra. Their commutators are easy to compute.

$$[S^i, S^j] = 2i\epsilon_{ijk}S^k, \quad [T^i, T^j] = 2i\epsilon_{ijk}T^k, \quad (6)$$

$$[S^i, T^j] = 0, \quad (7)$$

$$[S^i, K^{jk}] = 2i\epsilon_{ijl}K^{lk}, \quad [T^i, K^{jk}] = 2i\epsilon_{ikl}K^{jl}, \quad (8)$$

$$[K^{ij}, K^{kl}] = 2i\epsilon_{ikm}S^m\delta_{jl} + 2i\epsilon_{jln}T^n\delta_{ik} \quad (9)$$

Under this choice of basis, the 4 states are labeled by the eigenvalues of σ^z and τ^z . We will use the following short-hand notation

$$|1, 1\rangle = |1\rangle_\sigma \otimes |1\rangle_\tau = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = (1, 0, 0, 0)^T. \quad (10)$$

And similarly for the other 3 states $|-1, 1\rangle, |1, -1\rangle, |-1, -1\rangle$. In this basis, the classical AT model can be rewritten as

$$H = - \sum_{\langle i,j \rangle} [J_1 S_i^3 S_j^3 + J_2 T_i^3 T_j^3 + J_4 K_i^{33} K_j^{33}] \quad (11)$$

We now list both the internal and the lattice symmetries of this classical model.

1. Internal symmetries:

The classical AT model has an obvious global continuous symmetry $U(1)_{S^3} \times U(1)_{T^3} \times U(1)_{K^{33}}$ which is the rotation around S^3 , T^3 and K^{33} generated by the rotation matrix $U(\theta) = e^{i\theta_1 S^3/2} e^{i\theta_2 T^3/2} e^{i\theta_3 K^{33}/2}$. This is the only continuous symmetry of the model and implies that the phase differences between the four states are arbitrary. Any quantum term will break this symmetry.

The classical model also possess several discrete symmetries. We will argue that the quantum terms should preserve the discrete symmetries.

Like the Ising model, the classical AT model has a global Z_2 symmetry which maps σ^z to $-\sigma^z$. Since all the interaction terms involve two σ^z , they stay invariant. Similarly, we also have another Z_2 symmetry which maps τ^z to $-\tau^z$.

We are more interested in the symmetric case, $J_1 = J_2$. In this case, there is also a discrete symmetry Z_4 which is the symmetry under cyclic permutation among the 4 states. Since the coefficient of S^3 and T^3 terms are the same, the Hamiltonian is the invariant under this transformation. There is another Z_2 symmetry which switch σ and τ .

2. Lattice symmetry

The 4 states represent the loop current pattern on the square lattice of copper and oxygens. The point group of a square lattice is D_4 . It consists of 4-fold rotations and reflection about the x-axes, the y-axes and the two diagonal axes. The loop current states can be thought as currents flow along both x and y axes and the values of σ^z and τ^z label the directions of these currents. From these, one can find out how the point group of lattice act on these 4 state.

The 4-fold rotation makes the following transformation $|1, 1\rangle \rightarrow |-1, 1\rangle \rightarrow |-1, -1\rangle \rightarrow |1, -1\rangle \rightarrow |1, 1\rangle$ which is the same as the internal Z_4 symmetry. The transformation matrix is given by

$$C_4 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{pmatrix} \quad (12)$$

If we think of $|1, 1\rangle$ as a plane vector $(1, 1)$, then the above transformation makes a $\pi/2$ anti-clockwise rotation, which realizes the cyclic permutation among the 4 vectors. Then one can find out the following transformation

$$C_4 S^3 C_4^\dagger = -T^3, \quad C_4 T^3 C_4^\dagger = S^3, \quad C_4 K^{33} C_4^\dagger = -K^{33} \quad (13)$$

Clearly, the classical AT model is invariant under this transformation.

Now we turn to the reflections. The reflection about x-axes switches $|\pm 1, 1\rangle$ with $|\pm 1, -1\rangle$, which is also equivalent to the Ising like internal Z_2 symmetry. This reflection can be generated by operator $\sigma(0) = T^1$. Similarly, the reflection about y-axes switches $|1, \pm 1\rangle$ with $|-1, \pm 1\rangle$ and is generated by operator $\sigma(\pi/2) = S^1$. The reflection about $y = x$ switches $|1, -1\rangle$ and $|-1, 1\rangle$ and keep the other two states the same. This is the same

as the internal Z_2 symmetry $\sigma \leftrightarrow \tau$ and is generated by

$$\tilde{\sigma}(\pi/4) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad (14)$$

Similarly, the reflection about $y = -x$ switches $|1, 1\rangle$ and $|-1, -1\rangle$ and keeps the other two states the same. It is generated by $\tilde{\sigma}(3\pi/4) = S^1 T^1 \sigma(\pi/4)$ which is a combination of the 3 internal symmetries. One can see that all the internal discrete symmetries are coincident with the lattice symmetries. We expect that the quantum term preserve all the lattice symmetries, so it also preserve all the internal discrete symmetries.

3. Quantum terms allowed.

Now we want to identify possible terms which lead to the quantum fluctuations among the 4 classical states. In²⁶, the AT model has been mapped to XY model in the quantum-critical fluctuation regime of the phase diagram. In the loop ordered state, quantum term of AT model can be thought as a discrete version of the quantum term of XY model which makes clockwise and anti-clockwise rotations. As one can see, the unitary operator to generate anti-clockwise rotations is just C_4 we introduced. But since $\det C_4 = -1$, this operator is not a proper rotation in the complex 4D space but also includes a parity transformation e.g. $|1, 1\rangle \rightarrow -|1, 1\rangle$ and keep other 3 states which cannot be realized as a continuous transformation. Since the quantum evolution of states is obtained by integrating infinitesimal rotations, we expect the anti-clockwise rotation operator U to be a proper rotation, or $\det U = 1$. (This matter is further discussed in Appendix A). Therefore, we introduce a phase factor to correct the sign of the determinant.

$$U = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{pmatrix} e^{-i\pi/4}. \quad (15)$$

Then the possible quantum terms should be all the possible Hermitian combinations of this unitary operator:

$$U + U^\dagger = \frac{1}{\sqrt{2}}[S^1 + T^1 + (K^{23} - K^{32})] \quad (16)$$

$$i(U - U^\dagger) = \frac{1}{\sqrt{2}}[S^1 + T^1 - (K^{23} - K^{32})] \quad (17)$$

$$\frac{i}{2}[U^2 - (U^\dagger)^2] = K^{11} \quad (18)$$

Since $U^4 = -1$, we have $U^2 + (U^\dagger)^2 = 0$. Therefore the above are the only possible independent Hermitian combinations to quadratic order in U . In the most general case, all these terms should be present in the quantum AT model. For our problem, we need to constrain this

further to be consistent with the lattice symmetry. The 4-fold rotation operator C_4 commutes with U , thus there is no constraint due to 4-fold rotation. As discussed, the reflection operators $\tilde{\sigma}(0)$ and $\tilde{\sigma}(\pi/2)$ are equivalent to T^1 and S^1 , respectively. And, for the reflection about x and y axes and diagonal directions, we have

$$S^1(U + U^\dagger)S^1 = i(U - U^\dagger) \quad (19)$$

$$T^1(U + U^\dagger)T^1 = i(U - U^\dagger). \quad (20)$$

For reflection operator $\sigma(\pm\pi/4)$, we note that

$$\tilde{\sigma}(\pi/4)(U + U^\dagger)\tilde{\sigma}(\pi/4) = i(U - U^\dagger) \quad (21)$$

$$\tilde{\sigma}(3\pi/4)(U + U^\dagger)\tilde{\sigma}(3\pi/4) = i(U - U^\dagger). \quad (22)$$

K^{11} is invariant under all these 4 reflections. One can see that $S^1 + T^1$ is even under the reflections and $K^{23} - K^{32}$ is odd. Therefore, the lattice symmetry require the coefficient in front of $U + U^\dagger$ and $i(U - U^\dagger)$ to be the same in order to cancel out the odd part. In conclusion, the proper quantum term that respect all the lattice symmetry should be $S^1 + T^1$ and K^{11} .

Even if we do not start with the rotation operator U , we will get the same results for the quantum term just by imposing lattice symmetry. In the chosen basis, the only diagonal matrices are S^3 , T^3 and K^{33} and they form a Cartan sub-algebra²⁷ of the $SU(4)$ Lie algebra, which is the maximal commuting sub-algebra one can find. All the other 12 generators contains non-zero off-diagonal elements and act as raising and lowering operators, which mix among the 4 states. The most general quantum term should be the superposition of all these 12 generators. Lattice symmetry requires that the quantum term commute with S^1 , T^1 , K^{11} and $\tilde{\sigma}(\pi/4)$. It is easy to see that S^1 , T^1 , K^{11} commute with each other thus they also form a Cartan sub-algebra. Therefore, the only generators which commute with S^1 , T^1 , K^{11} are themselves. $\tilde{\sigma}(\pi/4)$ switches S^1 with T^1 , thus require the coefficients of S^1 and T^1 to be the same. Thus the quantum term $S^1 + T^1$ and K^{11} is unique up to some unitary transformations.

It may seem strange that only the generators with 1 component are involved in the quantum term. Actually, this is only due to the specific choice of representation we have made. We can redefine $\tilde{\sigma}(0)$ and $\tilde{\sigma}(\pi/2)$ as $\tilde{\sigma}(0)|1, 1\rangle = e^{\phi_1}|1, -1\rangle$ and $\tilde{\sigma}(\pi/2)|1, 1\rangle = e^{\phi_2}|-1, 1\rangle$

$$\tilde{\sigma}(0) = I \otimes \begin{pmatrix} 0 & e^{\phi_1} \\ e^{-\phi_1} & 0 \end{pmatrix} = T^1 \cos \phi_1 - T^2 \sin \phi_1 \quad (23)$$

$$\tilde{\sigma}(\pi/2) = \begin{pmatrix} 0 & e^{\phi_2} \\ e^{-\phi_2} & 0 \end{pmatrix} \otimes I = S^1 \cos \phi_2 - S^2 \sin \phi_2. \quad (24)$$

Since the D_4 group can be generated by 2 elements, once the phase factor in $\tilde{\sigma}(0)$ and $\tilde{\sigma}(\pi/2)$ are fixed, phase of all other D_4 operators are also determined. In general, there are three arbitrary phase difference one can choose, but in the symmetric case, there are only two left. The other symmetry operators are obtained from $C_4^2 = \tilde{\sigma}(\pi/2)\tilde{\sigma}(0)$, $\tilde{\sigma}(\pi/4) = C_4\tilde{\sigma}(0)$ and $\tilde{\sigma}(3\pi/2) = C_4^2\tilde{\sigma}(\pi/4)$. As before,

$\tilde{\sigma}(0)$, $\tilde{\sigma}(\pi/2)$ and $\tilde{\sigma}(\pi/2)\tilde{\sigma}(0)$ form maximal commuting sub-algebra. Therefore the quantum terms are given by $\tilde{\sigma}(0) + \tilde{\sigma}(\pi/2)$ and $\tilde{\sigma}(\pi/2)\tilde{\sigma}(0)$ with both x and y component present. The new $\tilde{\sigma}(0)$, $\tilde{\sigma}(\pi/2)$ are related to the old ones by unitary transformations

$$\begin{aligned} e^{i(\phi_1 T^3 + \phi_2 S^3)/2} S^1 e^{-i(\phi_1 T^3 + \phi_2 S^3)/2} &= \tilde{\sigma}(\pi/2) \\ e^{i(\phi_1 T^3 + \phi_2 S^3)/2} T^1 e^{-i(\phi_1 T^3 + \phi_2 S^3)/2} &= \tilde{\sigma}(0). \end{aligned} \quad (25)$$

Thus the results for energy of the collective modes (but not their eigenvectors or the ground state wave-function) should remain the same as in the original gauge.

III. DISPERSION OF COLLECTIVE MODES

In the $SU(4)$ formalism, the classical Ashkin Teller model can be written as

$$H_{AT} = - \sum_{\langle i, j \rangle} [J_1 S_i^3 S_j^3 + J_2 T_i^3 T_j^3 + J_4 K_i^{33} K_j^{33}] \quad (26)$$

According to the discussion of section II, the quantum fluctuations can be described by the Ashkin Teller model with a symmetric quantum terms or transverse field as $S^1 + T^1$ and K^{11} . The Hamiltonian for the quantum Ashkin-Teller model is therefore given by

$$\begin{aligned} H_{AT}^Q &= \sum_i [t(S_i^1 + T_i^1) + t' K_i^{11}] \\ &- \sum_{\langle i, j \rangle} [J_1 S_i^3 S_j^3 + J_2 T_i^3 T_j^3 + J_4 K_i^{33} K_j^{33}] \end{aligned} \quad (27)$$

As discussed earlier, the basis of 4 states at each lattice site correspond to the 4 types of loop current states. In the AT model, these 4 states are labeled by the eigenvalues of σ^z and τ^z which can be denoted as $|\pm 1, \pm 1\rangle$. The kinetic term S^1 flips the sign of first index and T^1 flips the second. Then K^{11} flips both indices together. If we think of the two indices as x and y components of a plane vectors, the 4 states can also be represented by 4 plane vectors. Then S^1 and T^1 rotates the vector by $\pi/2$ and K^{11} rotates the vectors by π . In principle the parameters in this model should be determined from microscopic models. We will treat them as phenomenological parameters and determine them by fitting the observed dispersion of the collective modes, and judge if they have the scale of values expected, which is of the order of the pseudo-gap energy.

A. The Ground State

In order to calculate the collective mode dispersion, we first determine the ground state in the ordered phase at the mean field level. For the loop current ordered phase the classical AT model has ferromagnetic interactions $J_{1,2} > 0$ and $J_4 < |J_{1,2}|$, the latter to ensure that

there is no divergence of the specific heat at the transition. In this phase, we have $\langle S^3 \rangle \neq 0$, $\langle T^3 \rangle \neq 0$ and $\langle K^{33} \rangle \neq 0$. The most general uniform quantum ground state is a product over all sites of the linear combination of the 4 basis states. Since the overall complex factor is redundant, one can parameterize this state by 6 real parameters. Thus we assume the ground state to be

$$|G\rangle_0 = \prod_i \cos \frac{\theta_1}{2} \left(\cos \frac{\theta_2}{2} |1, 1\rangle_i + \sin \frac{\theta_2}{2} e^{i\phi_2} |1, -1\rangle_i \right) \\ + \sin \frac{\theta_1}{2} e^{i\phi_1} \left(\cos \frac{\theta_3}{2} |-1, 1\rangle_i \right. \\ \left. + \sin \frac{\theta_3}{2} e^{i\phi_3} |-1, -1\rangle_i \right) \quad (28)$$

It is straightforward to compute the energy per site E_g but the result is very complicated and we have to use numerics to minimize E_g to find out parameters θ_i and ϕ_i . Since the Hamiltonian does not involve the 2 component matrices and only 2 component matrices are imaginary, we expect the 3 phase parameters $\phi_i = 0$ for $i = 1, 2, 3$. Thus all the 4 coefficients are real numbers. This can be checked by numerical minimization of the energy. In comparing with experiments, we are more interested in a special case that $J_1 = J_2 = J$ and the Hamiltonian is invariant under the interchanging between σ and τ . In this case, we still have to numerically minimize E_g , but we find that the result can be well approximated by a direct product state

$$|G\rangle = \prod_i \left(\cos \frac{\theta}{2} |1\rangle_i + \sin \frac{\theta}{2} |-1\rangle_i \right)_\sigma \\ \otimes \left(\cos \frac{\theta}{2} |1\rangle_i + \sin \frac{\theta}{2} |-1\rangle_i \right)_\tau \quad (29)$$

which is parameterized by one angle θ . Then the angle is determined by equation,

$$t + t' \sin \theta + 4J \sin \theta + 4J_4 \sin \theta \cos^2 \theta = 0. \quad (30)$$

We will use this direct product ground state $|G\rangle$ for latter discussions. The energy of this direct product ground state is only 3% higher than the most general ground state, so it is a good approximation. We emphasize that this wave-function is in a particular gauge; the change of gauge, Eqs. (25), changes the ground state wave-function.

B. Collective Modes

To compute the spin wave like collective modes in this quantum Ashkin-Teller model, we generalize the Holstein-Primakoff transformation for $SU(2)$ to $SU(4)$. Introducing three boson operators b_i , c_i and d_i , we have the following boson operator representations for the Ashkin-Teller model (For ease of notation, we omit the

lattice site label i):

$$S^1 = Uc + c^\dagger U + b^\dagger d + d^\dagger b, \\ S^3 = 1 - 2c^\dagger c - 2d^\dagger d, \\ T^1 = Ub + b^\dagger U + c^\dagger d + d^\dagger c, \\ T^3 = 1 - 2b^\dagger b - 2d^\dagger d, \\ K^{11} = Ud + d^\dagger U + b^\dagger c + c^\dagger b, \\ K^{33} = 1 - 2b^\dagger b - 2c^\dagger c, \\ K^{13} = Uc + c^\dagger U - b^\dagger d - d^\dagger b, \\ K^{31} = Ub + b^\dagger U - c^\dagger d - d^\dagger c,$$

with $U = (1 - b^\dagger b - c^\dagger c - d^\dagger d)^{1/2}$. In this representation, we take the *classical* ground state such that $\langle S_i^3 \rangle = \langle T_i^3 \rangle = \langle K_i^{33} \rangle = 1$. Thus the *classical* ground state is just $|1, 1\rangle$ and $b_i^\dagger$, $c_i^\dagger$, $d_i^\dagger$ are the creating operators of states $|1, -1\rangle$, $|-1, 1\rangle$ and $|-1, -1\rangle$ at site i from the classical ground state respectively.

Due to the quantum terms, the mean field ground state $|G\rangle$ is a superposition of the 4 states at each site. In order to make use of the Holstein-Primakoff transformation, we can make a basis rotation to transform the ground state $|G\rangle$ to $\prod_i |1, 1\rangle_i$ in the new basis.

In the following calculations, we still keep J_1 and J_2 as two different parameters. In the last step, we will take $J_1 = J_2 = J$. For the direct product ground state $|G\rangle = \prod_i \left(\cos \frac{\theta_1}{2} |1\rangle_i + \sin \frac{\theta_1}{2} |-1\rangle_i \right)_\sigma \otimes \left(\cos \frac{\theta_2}{2} |1\rangle_i + \sin \frac{\theta_2}{2} |-1\rangle_i \right)_\tau$, the rotation we need is just two rotations around y axes by angle $\theta_{1,2}$ in the σ and τ space.

$$S^3 \rightarrow S^3 \cos \theta_1 - S^1 \sin \theta_1 \quad T^3 \rightarrow T^3 \cos \theta_2 - T^1 \sin \theta_2 \\ S^1 \rightarrow S^3 \sin \theta_1 + S^1 \cos \theta_1 \quad T^1 \rightarrow T^3 \sin \theta_2 + T^1 \cos \theta_2$$

Then the Hamiltonian is

$$H = \sum_i [t(S_i^3 s_1 + S_i^1 c_1) + t(T_i^3 s_2 + T_i^1 c_2)] \\ + t'(K_i^{33} s_1 s_2 + K_i^{31} s_1 c_2 + K_i^{13} c_1 s_2 + K_i^{11} c_1 c_2) \\ - \sum_{i,j} \left[J_1 (S_i^3 S_j^3 c_1^2 - S_i^3 S_j^1 c_1 s_1 - S_i^1 S_j^3 c_1 s_1 + S_i^1 S_j^1 s_1^2) \right. \\ \left. + J_2 (T_i^3 T_j^3 c_2^2 - T_i^3 T_j^1 c_2 s_2 - T_i^1 T_j^3 c_2 s_2 + T_i^1 T_j^1 s_2^2) \right] \\ - J_4 \sum_{i,j} (K^{33} c_1 c_2 - K^{31} c_1 s_2 - K^{13} s_1 c_2 + K^{11} s_1 s_2)_i \\ \times (K^{33} c_1 c_2 - K^{31} c_1 s_2 - K^{13} s_1 c_2 + K^{11} s_1 s_2)_j. \quad (31)$$

with $c_{1,2} = \cos \theta_{1,2}$ and $s_{1,2} = \sin \theta_{1,2}$. The $\theta_{1,2}$ can be solved from the equations.

$$t + t' s_2 + 4J_1 s_1 + 4J_4 s_1 c_2^2 = 0 \\ t + t' s_1 + 4J_2 s_2 + 4J_4 s_2 c_1^2 = 0$$

1. Simple Case, $J_4 = t' = 0$

We can start from the simple case with $J_4 = 0$ and $t' = 0$. In this case, the Hamiltonian is two decoupled

Ising models. We can plug in the boson transformation, expand the square root up to quadratic order. Since we only care about the collective mode dispersion, the constant term can be ignored. The linear terms in boson

operators will cancel out due to the minimization condition of the ground state energy. Thus we are only left with quadratic terms,

$$H_0 = t \sum_i [(-2c^\dagger c - 2d^\dagger d)_i s_1 + (b^\dagger d + d^\dagger b)_i c_1] - J_1 \sum_{i,j} \left[(-2c^\dagger c - 2d^\dagger d)_i c_1^2 + (-2c^\dagger c - 2d^\dagger d)_j c_1^2 - (b^\dagger d + d^\dagger b)_i s_1 c_1 - (b^\dagger d + d^\dagger b)_j s_1 c_1 + (c + c^\dagger)_i (c + c^\dagger)_j s_1^2 \right] + \text{terms } (b \leftrightarrow c, 1 \leftrightarrow 2). \quad (32)$$

This equation can be simplified by using identity $-ts_i + 4J_i c_i^2 = 4J_i$. Note that $(b^\dagger d + d^\dagger b)$ and $(c^\dagger d + d^\dagger c)$ terms cancels out, thus operator d decoupled from b and c . In momentum space we have

$$H_0 = \sum_{\mathbf{k}} (4J_1 - 2J_1 s_1^2 f_{\mathbf{k}}) (c_{\mathbf{k}}^\dagger c_{\mathbf{k}} + c_{-\mathbf{k}} c_{-\mathbf{k}}^\dagger) - 2J_1 s_1^2 f_{\mathbf{k}} (c_{\mathbf{k}} c_{-\mathbf{k}} + c_{\mathbf{k}}^\dagger c_{-\mathbf{k}}^\dagger) + (4J_2 - 2J_2 s_2^2 f_{\mathbf{k}}) (b_{\mathbf{k}}^\dagger b_{\mathbf{k}} + b_{-\mathbf{k}} b_{-\mathbf{k}}^\dagger) - 2J_2 s_2^2 f_{\mathbf{k}} (b_{\mathbf{k}} b_{-\mathbf{k}} + b_{\mathbf{k}}^\dagger b_{-\mathbf{k}}^\dagger) + 8(J_1 + J_2) d_{\mathbf{k}}^\dagger d_{\mathbf{k}}. \quad (33)$$

One can see that the three sets of 3 bosons are decoupled. The b and c part are two copy of Ising models and the d part is free boson. Making use of standard Bogoliubov transformation we can diagonalize the above Hamiltonian and find the following dispersions

$$\begin{aligned} \omega_1 &= 2[(4J_1)^2 - t^2 f_{\mathbf{k}}]^{1/2}, \\ \omega_2 &= 2[(4J_2)^2 - t^2 f_{\mathbf{k}}]^{1/2}, \\ \omega_3 &= 8(J_1 + J_2). \end{aligned}$$

In addition to the two Ising model modes, we also find a third mode which is dispersion-less. The two Ising modes are generated by bosons operators b and c which only rotate σ or τ space alone. Since the ground state is a direct product, the excited state generated by modes b and c are also direct products.

$$\begin{aligned} \exp(-i\phi b)|1, 1\rangle &\approx |1, 1\rangle - i\phi|1, -1\rangle \\ &= |1\rangle \times (|1\rangle - i\phi|-1\rangle). \end{aligned} \quad (34)$$

On the other hand, the third mode which is generated by boson operator d cannot be written as a direct product. For example,

$$\exp(-i\phi d)|G_0\rangle \approx |1, 1\rangle - i\phi|-1, -1\rangle, \quad (35)$$

which cannot be written in the form: $|\psi_\sigma\rangle \otimes |\psi_\tau\rangle$.

The constant energy feature of the third mode can be explained as follows. The Hamiltonian with $J_4 = 0$ in the rotated basis is the first 2 lines of Eq. (31). If we linearize the Hamiltonian, then we have following terms

involving S ,

$$- \sum_i 4JS^3 - J \sum_{i,j} S_i^1 S_j^1 s_1^2. \quad (36)$$

The first terms describes the rotation of S spin under a z direction constant external field for all lattice sites. If we only keep this term, we will only get a constant dispersion $4J$. Since now the ground state is up spin for all lattice sites and S^1 can flip up spin to down spin, the term $S_i^1 S_j^1 \sin^2 \theta$ describes an interaction between the flip in site i and neighboring site j . Thus the spin flip can propagate and give a plane wave momentum dependence like $f_{\mathbf{k}} s_1^2$, which agrees with our previous result. The third mode corresponds to spin flip: $|1, 1\rangle \rightarrow |-1, -1\rangle$. In order to make this flip propagate, one need a term like $K_i^{11} K_j^{11}$ in the Hamiltonian. But when $J_4 = 0$ there is no such terms, thus the third modes is constant when $J_4 = 0$. When $J_4 \neq 0$, we have a term $K_i^{11} K_j^{11} s_1^2 s_2^2$ in Eq (31). and the third mode will acquire momentum dependence.

2. General Case

Now we turn to the general case when $J_4 \neq 0$ and $t' \neq 0$. The t' and J_4 terms involve operators like K_{11} and K_{33} which couple the σ and τ spin and split the two degenerate modes we obtained in the decoupled case. We denote these two terms by H' . Transforming to the boson representation we have

$$\begin{aligned}
H' = t' \sum_i & \left[(-2b^\dagger b - 2c^\dagger c)_i s_1 s_2 + (-c^\dagger d - d^\dagger c)_i s_1 c_2 + (-b^\dagger d - d^\dagger b)_i c_1 s_2 + (b^\dagger c + c^\dagger b)_i c_1 c_2 \right] \\
& - 2J_4 \sum_i \left[2(-2b^\dagger b - 2c^\dagger c)_i c_1^2 c_2^2 + 2(c^\dagger d + d^\dagger c)_i c_1^2 s_2 c_2 + 2(b^\dagger d + d^\dagger b)_i s_1 c_1 c_2^2 + 2(b^\dagger c + c^\dagger b)_i s_1 c_1 s_2 c_2 \right. \\
& + \sum_j (b + b^\dagger)_i (b + b^\dagger)_j c_1^2 s_2^2 + \sum_j (c + c^\dagger)_i (c + c^\dagger)_j s_1^2 c_2^2 + \sum_j (d + d^\dagger)_i (d + d^\dagger)_j s_1^2 s_2^2 \\
& \left. + 2 \sum_j (b + b^\dagger)_i (c + c^\dagger)_j s_1 c_1 s_2 c_1 - 2 \sum_j (b + b^\dagger)_i (d + d^\dagger)_j s_1 c_1 s_2^2 - 2 \sum_j (c + c^\dagger)_i (d + d^\dagger)_j s_1^2 s_2 c_2 \right].
\end{aligned}$$

We can make use of identities like $-ts_1 - t's_1 s_2 + 4J_1 c_1^2 + 4J_4 c_1^2 c_2^2 = 4(J_1 + J_4 c_2^2)$ to simplify the above equation. Transforming to momentum space and combining with H_0 , the total Hamiltonian is (we drop the subscript $\mathbf{k}$ to simplify the notation)

$$\begin{aligned}
H = \sum_{\mathbf{k}} & (J_2 + J_4 c_1^2) [8b^\dagger b - 2s_2^2 f_{\mathbf{k}} (b + b^\dagger)^2] + (J_1 + J_4 c_2^2) [8c^\dagger c - 2s_1^2 f_{\mathbf{k}} (c + c^\dagger)^2] \\
& + \left[8(J_1 c_1^2 + J_2 c_2^2) - 2t(s_1 + s_2) \right] d^\dagger d - 2J_4 s_1^2 s_2^2 f_{\mathbf{k}} (d + d^\dagger)^2 \\
& + 2(t + 4J_1 s_1) c_1 (b^\dagger d + d^\dagger b) + 2(t + 4J_2 s_2) c_2 (c^\dagger d + d^\dagger c) + (t' - 4J_4 s_1 s_2) c_1 c_2 (b^\dagger c + c^\dagger b) \\
& - 4J_4 \left[s_1 c_1 s_2 c_1 f_{\mathbf{k}} (b + b^\dagger)(c + c^\dagger) - s_1 c_1 s_2^2 f_{\mathbf{k}} (b + b^\dagger)(d + d^\dagger) - s_1^2 s_2 c_2 f_{\mathbf{k}} (c + c^\dagger)(d + d^\dagger) \right], \quad (37)
\end{aligned}$$

with $f_{\mathbf{k}} = (\cos k_x + \cos k_y)/2$. We can rewrite the Hamiltonian (37) in a matrix form $H = \psi^\dagger M \psi$ with $\psi = (b^\dagger, b, c^\dagger, c, d^\dagger, d)^T$ and the 6 by 6 symmetric M . There are only 12 independent elements because the matrix elements are the same under the interchange $1 \leftrightarrow 2$, $3 \leftrightarrow 4$ and $5 \leftrightarrow 6$ for both indices or by interchanging the position of the two indices $ij \leftrightarrow ji$. These matrix elements are easy to read off from Eq. (37).

Since the Hamiltonian is quadratic, one can use standard Bogoliubov transformation to diagonalize the above Hamiltonian and find the collective mode dispersions. We introduce the following quasi-particle creation and annihilation operators

$$\begin{aligned}
b &= u_{11}\alpha + v_{11}\alpha^\dagger + u_{12}\beta + v_{12}\beta^\dagger + u_{13}\gamma + v_{13}\gamma^\dagger \\
c &= u_{21}\alpha + v_{21}\alpha^\dagger + u_{22}\beta + v_{22}\beta^\dagger + u_{23}\gamma + v_{23}\gamma^\dagger \\
d &= u_{31}\alpha + v_{31}\alpha^\dagger + u_{32}\beta + v_{32}\beta^\dagger + u_{33}\gamma + v_{33}\gamma^\dagger.
\end{aligned}$$

This introduces 18 real parameters u_{ij}, v_{ij} for $i, j = 1, 2, 3$. In order to make the quasi-particles to be bosons we require that the only non zero commutators are $[\alpha, \alpha^\dagger] = [\beta, \beta^\dagger] = [\gamma, \gamma^\dagger] = 1$. This leads to the following constraint

$$\begin{aligned}
\sum_{m=1}^3 (u_{im}^2 - v_{im}^2) &= 1 \\
\sum_{m=1}^3 \epsilon_{ijk} (u_{im} v_{jm} - v_{im} u_{jm}) &= 0 \\
\sum_{m=1}^3 \epsilon_{ijk} (u_{im} u_{jm} - v_{im} v_{jm}) &= 0. \quad (38)
\end{aligned}$$

for $i, j, k = 1, 2, 3$. There are 9 constraints, thus we are left with 9 free parameters.

Thus there are only 9 independent elements in Hamiltonian so that the off-diagonal 9 can be set to zero by adjusting the 9 free parameters among u and v . Then we are left with a diagonal Hamiltonian and 3 dispersion modes. But it is very difficult to explicitly solve the 18 real parameters u and v . It is easier to determine the the dispersions directly. But this can not be done by directly diagonalize M , because u and v do not form a unitary matrix. Introducing $\phi = (\alpha^\dagger, \alpha, \beta^\dagger, \beta, \gamma^\dagger, \gamma)^T$, the Bogoliubov transformation can be rewritten as $\psi = U\phi$. One can verify that $U^\dagger U \neq 1$. This is because $\psi^\dagger \psi \neq \phi^\dagger \phi$ and $\psi^\dagger \psi$ cannot be treat as the norm of the vector ψ . This can be fixed by introducing matrix $\sigma = \text{diag}\{1, -1, 1, -1, 1, -1\}$, then we have $\psi^\dagger \sigma \psi = [b, b^\dagger] + [c, c^\dagger] + [d, d^\dagger] = 3$ and similarly $\phi^\dagger \sigma \phi = 3$. Thus we have $U^\dagger \sigma U = \sigma$. This can also be written as $\sigma U^\dagger \cdot \sigma U = I$ and $\sigma U \cdot \sigma U^\dagger = I$. One can verify that the last equation is consistent with the constraints in Eq. (38).

Suppose we have determined the parameters u and v that diagonalize the Hamiltonian, then we have $U^\dagger M U = \text{diag}\{\omega_1, \omega_1, \omega_2, \omega_2, \omega_3, \omega_3\}$ and $\omega_{1,2,3}$ are the three excitation modes. We can rewrite this as

$$\sigma U^\dagger \cdot M \sigma \cdot \sigma U = \text{diag}\{\omega_1, -\omega_1, \omega_2, -\omega_2, \omega_3, -\omega_3\} \quad (39)$$

It is easy to see that

$$\begin{aligned}
& \det(\sigma U^\dagger \cdot M \sigma \cdot \sigma U - \omega I) \\
&= \det(\sigma U^\dagger) \det(M \sigma - \omega I) \det(\sigma U) = \det(M \sigma - \omega I)
\end{aligned}$$

thus matrix $\sigma U^\dagger \cdot M \sigma \cdot \sigma U$ and $M \sigma$ have same eigenvalues. We can determine the dispersion of the three modes by

solving the equation

$$\det(M\sigma - \omega I) = 0 \quad (40)$$

which is a cubic equation in ω^2 . We determine the roots numerically. We again find 3 collective modes but now all of them are weakly dispersive.

Actually we are more interested in the special case $J_1 = J_2$. In this case, one can further simplify the equa-

tion by introducing symmetrized and anti-symmetrized variables $a_1 = (b+c)/\sqrt{2}$ and $a_2 = (b-c)/\sqrt{2}$. Then the 6 by 6 matrix will decompose into one 4 by 4 matrix for symmetrized operator a_1 and d and one 2 by 2 matrix for anti-symmetrized operator a_2 . Now the eigenvalues of symmetrized operator a_1 and d are

$$\omega_{1,3} = \left[2(A_s A_d + B_s B_d + 2C_s C_d) \pm 2\sqrt{(A_s A_d + B_s B_d + 2C_s C_d)^2 - 4(A_s B_s - C_s^2)(A_d B_d - C_d^2)} \right]^{1/2} \quad (41)$$

with $A_{s,d} = A_1 \pm A_2$ and the same for $B_{s,d}$ and $C_{s,d}$. Here we have $A_1 = 2J(2 - s^2 f_{\mathbf{k}}) - 2J_4 c^2 [-2 + (1 + 2f_{\mathbf{k}})s^2] + t' c^2 / 2$, $A_2 = -2(J + 2J_4 c^2)s^2 f_{\mathbf{k}}$, $B_1 = 8Jc^2 - 2ts - 2J_4 s^4 f_{\mathbf{k}}$, $B_2 = -2J_4 s^4 f_{\mathbf{k}}$, $C_1 = \sqrt{2}c(t + 4Js + 2J_4 s^3 f_{\mathbf{k}})$ and $C_2 = 2\sqrt{2}J_4 s^3 c f_{\mathbf{k}}$ with $s = \sin \theta$ and $c = \cos \theta$. The eigenvalues of anti-symmetrized operator a_2 is

$$\omega_2 = \left[\left(8J + 2J_4 c^2(2 + s^2) - t' c^2 \right) \left(8J + 2J_4 c^2(2 + s^2) - t' c^2 - 8J s^2 f_{\mathbf{k}} \right) \right]^{1/2} \quad (42)$$

In order to get a qualitative picture of these three modes, we can numerically compute some typical eigenvectors. For example, take the point at zone boundary $k_x = \pi/a$, $k_y = 0$. The three eigen-modes are created by the following quasi-particle operators

$$\begin{aligned} \alpha^\dagger &= 0.67(b^\dagger + c^\dagger) - 0.3d^\dagger, \\ \beta^\dagger &= 0.71(b^\dagger - c^\dagger), \\ \gamma^\dagger &= 0.21(b^\dagger + c^\dagger) + 0.95d^\dagger \end{aligned}$$

One can see that the first and third modes symmetrically mix $|1, 1\rangle \rightarrow |1, -1\rangle + |-1, 1\rangle$ and $|1, 1\rangle \rightarrow |-1, -1\rangle$. The

first mode has more weight on the former and third one has weight on the latter. On the other hand the second mode mixes $|1, 1\rangle \rightarrow |1, -1\rangle - |-1, 1\rangle$ anti-symmetrically.

In the decoupled limit, we have two degenerate Ising modes for bosons b and c . In other word, these two modes are propagation of 90 degree flip. The third mode is constant corresponding to boson d or 180 degree flip. In general case with non-zero J_4 and t' , there is no degeneracy and the third mode is also dispersive. In order to understand the qualitative effects of J_4 , we first consider that $t' = 0$ and J_4 is small and then make a perturbation expansion as follows

$$\begin{aligned} \omega_1 &= \sqrt{16J^2 - f_{\mathbf{k}} t^2} + \frac{16J^2 - t^2}{\sqrt{16J^2 - f_{\mathbf{k}} t^2}} \left[1 - (1 + f_{\mathbf{k}}) \frac{t^2}{32J^2} - f_{\mathbf{k}} \frac{t^4}{1024J^4} \right] \frac{J_4}{J} \\ \omega_2 &= \sqrt{16J^2 - f_{\mathbf{k}} t^2} + \frac{32J^2 - f_{\mathbf{k}} t^2}{\sqrt{16J^2 - f_{\mathbf{k}} t^2}} \left[\frac{1}{2} - \frac{3t^2}{64J^2} + \frac{t^4}{1024J^4} \right] \frac{J_4}{J} \\ \omega_3 &= 8J + \left[\frac{t^2}{2J^2} - (4 + f_{\mathbf{k}}) \frac{t^4}{128J^4} \right] J_4 \end{aligned}$$

We can also assume that $J_4 = 0$ and t' is small then make a perturbation expansion as follows

$$\begin{aligned} \omega_1 &= \sqrt{16J^2 - f_{\mathbf{k}} t^2} + \frac{J^2}{\sqrt{16J^2 - f_{\mathbf{k}} t^2}} \left[-2 + (2 + 5f_{\mathbf{k}}) \frac{t^2}{16J^2} - f_{\mathbf{k}} \frac{t^4}{256J^4} \right] \frac{t'}{J} \\ \omega_2 &= \sqrt{16J^2 - f_{\mathbf{k}} t^2} + \frac{J^2}{\sqrt{16J^2 - f_{\mathbf{k}} t^2}} \left[2 + (-2 + 3f_{\mathbf{k}}) \frac{t^2}{16J^2} + f_{\mathbf{k}} \frac{t^4}{256J^4} \right] \frac{t'}{J} \\ \omega_3 &= 8J + \frac{t^2}{8J^2} t' \end{aligned}$$

Qualitatively, both J_4 and t' split the dispersions of ω_1 and ω_2 , but J_4 also changes the relative dispersion of

these two modes. More precisely, positive J_4 makes ω_1

Figure 5: The collective mode dispersions of Ashkin-Teller model with negative J_4 as a function of k_x along the $k_x = k_y$ direction. The black curve stands for ω_1 and red curve stands for ω_2 . The parameters are taken to fit the experimental results in $Hg1201$, $T_c = 65K$. The blue curve gives the calculated third mode.

more dispersive than ω_2 and negative J_4 makes ω_1 less dispersive than ω_2 . On the other hand, t' mostly shifts the whole curve and makes both the modes more dispersive. Positive t' pushes ω_1 up and push ω_2 down, while negative t' does the opposite.

C. Damping

The principal source of the damping of the collective modes is the decay into particle-hole pairs, of similar energy and same symmetry as the collective modes, provided by H_{F-coll} . There exists a pseudo-gap in the single-particle fermion spectra in the same region of the phase diagram as the observed order. Therefore for energies of up to about 50 meV in the well under-doped region, damping of the collective modes is expected not to obscure their visibility. Still, it is surprising that the two observed branches of modes¹⁸ in $Hg1201$, $T_c = 61K$ have a damping smaller than the experimental resolution of about 5 meV. This may be due to the large magnitude of the order parameter so that most of the orbital current spectral weight of the appropriate symmetry which in the non-interacting model is in the incoherent fermion excitations is transferred to the collective excitations. It is possible that the third branch, which is at about 100 meV has a significantly higher damping.

IV. COMPARISON WITH MEASURED DISPERSION

We Choose parameters to reproduce the experiments¹⁸ in $Hg1201$ with $T_c = 61K$. The results are shown in Fig. (5). In the experiments, one of the collective modes is at 40 ± 5 meV another one at 50 ± 5 meV at $k = 0$. The dispersion across the Brillouin zone in both the (11) and the (10) directions for the higher energy mode is 5 ± 5 meV, while the lower mode is even less dispersive. We also have the very important constraint from the thermodynamics of the AT model^{24,28} that to have a transition with no divergence in the specific heat $-1 < J_4/J < 0$, $J > 0$. In Fig. (5), the following parameters are used:

$$\begin{aligned} t &= 3.9 \text{ meV}, & J &= 7.25 \text{ meV}, \\ J_4 &= -0.2J, & t' &= -2.15t. \end{aligned} \quad (43)$$

These give that $\sin \theta \approx -0.257$. The dispersion width of the first mode is about 10% of the energy gap and second one is around 5% of the energy gap. The results are shown in figure 5. These dispersions change with doping; we use a doping where a lot of data is available.

As discussed in Appendix D, the highest energy branch with eigenvalue ω_3 , is primarily an excitation with angular momentum 2 with a small admixture of angular momentum 1. The former are undetectable in neutron scattering experiments. This branch also has a higher energy than has currently been addressed by inelastic neutrons; it may also be an over-damped excitations since it lies well above the pseudo-gap energy in the single-particle spectra.

V. CONCLUSIONS

We find that with reasonable parameters, one can fit the measured dispersion of the rather unique collective modes in the loop ordered phase. The experimental discovery of these collective modes, whose appearance as a function of temperature coincides with the transition temperature of the loop ordered phase and whose intensity is consistent in its variation as the square of the measured order parameter as a function of temperature, adds further confidence to the existence of loop order. Indeed, there is no calculation we know of in which other proposed form of order give multiple weakly dispersive collective modes.

The energy of all the modes calculated should $\rightarrow 0$ for momentum $\mathbf{q} \rightarrow 0$, as $T \rightarrow T^*(x)$, the loop order temperature. We suggest experiments to verify this. It also follows that the spectral weight of these modes comes at the expense of the unusual local quantum fluctuations²⁶ in the marginal fermi-liquid region of the phase diagram of the cuprates. Accordingly, we expect a strong diminution of the low energy part of such fluctuations in the pseudo-gap region of the phase diagram.

When quantum terms are included, the ground state is a product over all unit-cells of the linear combinations

of the four classical configurations. Beyond mean-field calculations, the ground state is more complicated and includes effects due to the zero point fluctuations of the collective modes. Since the modes are Ising-like, this is a small change. We have estimated that the quantum correction to the expectations $\langle S^3 \rangle$, $\langle T^3 \rangle$ and $\langle K^{33} \rangle$ are smaller than 1%.

The mean-field ground state discovered here has important bearing on the effective angle with respect to the c-axis, deduced by elastic polarized neutron scattering experiments¹⁶. This is discussed in an accompanying paper. It also may have consequences for the gap in one-particle fermion spectra in the pseudo-gap regime. We hope to discuss this important matter in the near future.

Acknowledgments

We wish to acknowledge useful discussions of the experimental results and comparison with the calculations with Philippe Bourges, Martin Greven, Yuan Li, Herb Mook and Yvan Sidis. We have also benefitted from discussions with Vivek Aji and Thierry Giamarchi on several important issues.

Appendix A: AT model in $SO(6)$ spinor representation

In this appendix, we will rewrite the Ashkin-Teller model generators in terms of $SO(6)$ spinor representation²⁷. In this formalism, one can explicitly show that the spinor representation that requires $U^4 = -1$ instead of $U^4 = 1$. From group theory we know that locally $SU(4)$ is equivalent to $SO(6)$. More precisely, $SU(4)$ is a double cover of $SO(6)$. Thus the fundamental representation of $SU(4)$ we have used in the paper corresponds to the spinor representation of $SO(6)$. We can express U in terms of this spinor representation. The minimal dimension of gamma matrices of $SO(6)$ is 8. One can use the eigenvalues of γ_7 to define chiral spinor which is dimension 4, same as the fundamental representation of $SU(4)$. We can introduce the following 6 gamma matrices

$$\gamma_a = (\sigma^x \otimes S^2, \sigma^x \otimes S^3, \sigma^x \otimes K^{11}, \sigma^x \otimes K^{12}, \sigma^x \otimes K^{13}, \sigma^y \otimes I_4) \quad (A1)$$

and one can verify that they satisfy $\{\gamma_a, \gamma_b\} = 2\delta_{ab}$. Then the 15 generators of $SO(6)$ are given by $S_{ab} = \frac{1}{4i}[\gamma_a, \gamma_b]$ and they correspond to the 15 generators of $SU(4)$. They can be explicitly written as

$$S_{ab} = \frac{1}{2} \left(I \otimes S^1, I \otimes T^{1,2,3}, I \otimes K^{ij}, \sigma^z \otimes S^{2,3}, \sigma^z \otimes K^{1j} \right) \quad (A2)$$

with $i = 2, 3$ and $j = 1, 2, 3$. Note that all the above generators can be decomposed as two 4 by 4 blocks. The

same is true for $\gamma_7 = i\gamma_1 \cdots \gamma_6 = \sigma^z \otimes I_4$. The 8 dimension spinor thus decomposes into two 4 dimension chiral spinors according to $\gamma_7 = \pm 1$. The rotation operator can be written as

$$U = \exp \left[-i\frac{\pi}{4}(S^1 + T^1 - K^{23} + K^{32} - K^{11}) \right] \quad (A3)$$

The corresponding operator acting on the spinor space is

$$U' = \exp \left[-i\frac{\pi}{2}(S_{12} + S_{45} + S_{25} - S_{14} - S_{36}) \right] \quad (A4)$$

So this is a $\pi/2$ rotation of a 2d plane inside a 6D space. Then U'^4 is a 2π rotation in the 6D space. When it act on the spinors, it gives an extra minus sign, just as in the 4D Dirac spinor case. The same thing happened to U^4 since it act on the chiral spinors.

Appendix B: Need for $SU(4)$ formalism

In order to treat the 4 states on the equal footing, we enlarge the the $SU(2) \times SU(2)$ group to $SU(4)$ group. Actually, in the classical AT model, only S^3 , T^3 and K^{33} appear, and all of them are diagonal matrices and commute with each other and can be treat as numbers. Thus at the classical level there is no difference between $SU(2) \times SU(2)$ and $SU(4)$ formalism. But for the quantum model, this is no longer true. In the $SU(2) \times SU(2)$ formalism, all the quantum states are direct product $S^2 \times S^2$ and they can be parametrized by 4 real numbers. There are only two sets of raising and lowering operators which can be used as quantum flipping terms. In $SU(4)$ formalism, the space of all possible quantum states is CP_3 which is parametrized by 6 real numbers. There 6 sets of raising and lowering operators and they exhaust all possible rotations in CP_3 .

Therefore $SU(2) \times SU(2)$ can not make the most general unitary evolution in the 4 state system. Thus It can not treat all the rotations among the 4 states on the same footing. In the linear order, the only quantum flipping term is σ^x or τ^x or equivalent terms, which can switching between $\sigma^z = \pm 1$ or $\tau^z = \pm 1$. Other types of rotation such as cyclic permutation U can not be expressed as linear combinations of $SU(2) \times SU(2)$ generators. They have to be expressed in terms of high order power terms.

Appendix C: The collective modes in the $SU(2) \times SU(2)$ Formalism

Nevertheless, It is interesting to compute the collective modes of quantum AT model without enlarging the basis to $SU(4)$ but restrict to $SU(2) \times SU(2)$ group and compare the results. In this way, σ^i and τ^i are just 2 by 2 matrices. They correspond to S^i and T^i matrices in the $SU(4)$ basis. There is no operators correspond to K^{ij} in $SU(2) \times SU(2)$ basis and all the quantum states are direct product of two sets of Ising spin states. Now

Figure 6: The two modes in the $SU(2) \times SU(2)$ formalism.

we only have to introduce two HP bosons thus there are only two modes.

Now we introduce the HP boson as follows.

$$\begin{aligned}\sigma^x &= U_1 b + b^\dagger U_1, & \sigma^y &= -i(U_1 b - b^\dagger U_1), \\ \sigma^z &= 1 - 2b^\dagger b \\ \tau^x &= U_2 c + c^\dagger U_2, & \tau^y &= -i(U_2 c - c^\dagger U_2), \\ \tau^z &= 1 - 2c^\dagger c\end{aligned}$$

with $U = (1 - b^\dagger b)^{1/2}$ and with $U_2 = (1 - c^\dagger c)^{1/2}$.

We consider the simplest case.

$$\begin{aligned}H_{QAT} &= \sum_i [t(\sigma_i^x + \tau_i^x)] \\ &- \sum_{\langle i,j \rangle} [J\sigma_i^z \sigma_j^z + J\tau_i^z \tau_j^z + J_4 \sigma_i^z \sigma_j^z \tau_i^z \tau_j^z] \quad (C1)\end{aligned}$$

Now the ground state is

$$\begin{aligned}|G\rangle &= \left(\cos \frac{\theta}{2} |1\rangle + \sin \frac{\theta}{2} |-1\rangle \right)_\sigma \\ &\otimes \left(\cos \frac{\theta}{2} |1\rangle + \sin \frac{\theta}{2} |-1\rangle \right)_\tau \quad (C2)\end{aligned}$$

with θ being determined by $t + 4Js + 4J_4 s c^2 = 0$ with $s = \sin \theta$ and $c = \cos \theta$.

As before, we should first make a basis rotation to make the ground state satisfying $\langle \sigma^z \rangle = \langle \tau^z \rangle = 1$. Then we can plug in the HP representation and expand to quadratic order. In the momentum space, we find

$$\begin{aligned}H &= \sum_{\mathbf{k}} \left(-2tsb_k^\dagger b_k - 2J[-4(b_k^\dagger b_k)c^2 + (b_k + b_k^\dagger)^2 f_k s^2] \right. \\ &\quad \left. - 2tsc_k^\dagger c_k - 2J[-4(c_k^\dagger c_k)c^2 + (c_k + c_k^\dagger)^2 f_k s^2] \right. \\ &\quad \left. - 2J_4[-4c^4(b_k^\dagger b_k + c_k^\dagger c_k) + 2s^2 c^2(b_k + b_k^\dagger)(c_k + c_k^\dagger) + (b_k + b_k^\dagger + c_k + c_k^\dagger)^2 f_k s^2 c^2] \right) \quad (C3)\end{aligned}$$

Let $\psi = (b^\dagger, b, c^\dagger, c)^T$, then the Hamiltonian can be written as $H = \psi^\dagger M \psi$ with

$$M = \begin{pmatrix} 4J'(2 - s^2 f_k) & -4J' s^2 f_k & -4J_4 s^2 c^2(1 + f_k) & -4J_4 s^2 c^2(1 + f_k) \\ -4J' s^2 f_k & 4J'(2 - s^2 f_k) & -4J_4 s^2 c^2(1 + f_k) & -4J_4 s^2 c^2(1 + f_k) \\ -4J_4 s^2 c^2(1 + f_k) & -4J_4 s^2 c^2(1 + f_k) & 4J'(2 - s^2 f_k) & -4J' s^2 f_k \\ -4J_4 s^2 c^2(1 + f_k) & -4J_4 s^2 c^2(1 + f_k) & -4J' s^2 f_k & 4J'(2 - s^2 f_k) \end{pmatrix} \quad (C4)$$

Here $J' = J + J_4 c^2$.

Then we can diagonalize the above matrix and find the dispersion of the two collective modes

$$\omega_k = 8\sqrt{(J + J_4 c^2) \left[(J + J_4 c^2)(1 - s^2 f_k) \pm J_4 s^2 c^2(1 + f_k) \right]} \quad (C5)$$

If we let $J_4 = 0$, then we get $\omega_k = 8J(1 - s^2 f_k)^{1/2}$ which is the same as the Ising model solution. Since $f_k = -1$ for $k_x = k_y = \pi$, the two modes are degenerate at the zone corner.

We can still use the parameters from section III: $t = 3.9$, $J = 7.25$, $J_4 = -0.2J$ and $t' = 0$. Then we find the ground state parameter $\sin \theta = -0.34$. The two collective mode dispersions are plotted in figure 6. In this formalism, the two modes are always degenerate at the zone corner and the experimental results are not well

represented.

Appendix D: Inelastic neutron scattering

We present here the theory for the inelastic neutron scattering from the collective mode of the loop ordered phase. For calculating elastic neutron scattering³⁰, We approximate the loop current states as 4 spin 1 local moments. Based on the same formalism, we can also com-

pute the inelastic neutron scattering amplitude.

First, we need to express the local moment operator in terms of the generators of Ashkin-Teller model. We can make use of the local moments expression of the 4 loop

current states³⁰. Then the local spin operator at $\mathbf{R}_1$ can be obtained by $L_{\mathbf{R}_1}^i = \langle \psi, \mathbf{R}_1 | L^i | \psi', \mathbf{R}_1 \rangle$, with ψ, ψ' take the 4 possible loop current states.

$$\begin{aligned} L_{\mathbf{R}_1}^x &= L_{\mathbf{R}_2}^x = \frac{1}{2}(S^1 + T^1), & L_{\mathbf{R}_3}^x &= L_{\mathbf{R}_4}^x = -\frac{1}{2}(S^1 + T^1), \\ L_{\mathbf{R}_1}^y &= L_{\mathbf{R}_3}^y = \frac{1}{2}(S^2 + T^2), & L_{\mathbf{R}_2}^y &= L_{\mathbf{R}_4}^y = \frac{1}{2}(S^2 - T^2), \\ L_{\mathbf{R}_1}^z &= -L_{\mathbf{R}_3}^z = \frac{1}{2}(S^3 + T^3), & L_{\mathbf{R}_2}^z &= -L_{\mathbf{R}_4}^z = \frac{1}{2}(S^3 - T^3) \end{aligned}$$

Then the inelastic magnetic differential cross section can be expressed in terms of the correlation function of these local moment operators

$$\frac{d^2\sigma}{d\Omega dE'} = \frac{k'}{k} \sum_{\mu\nu} \sum_{a,b} (\delta_{\mu\nu} - \hat{q}_\mu \hat{q}_\nu) e^{i\mathbf{q} \cdot (\mathbf{R}_a - \mathbf{R}_b)} \int_{-\infty}^{\infty} \langle L_{\mathbf{q},a}^\mu(0) L_{\mathbf{q},b}^\nu(t) \rangle e^{-i\omega t} dt \quad (\text{D1})$$

As in the calculation of the collective mode, it is easy to compute the correlation function in terms of Holstein-Primakoff bosons. To the linear order, we find

$$\begin{aligned} L_{\mathbf{R}_1}^x &= L_{\mathbf{R}_2}^x = \frac{\cos\theta}{2}(b + b^\dagger + c + c^\dagger), & L_{\mathbf{R}_3}^x &= L_{\mathbf{R}_4}^x = -\frac{\cos\theta}{2}(b + b^\dagger + c + c^\dagger), \\ L_{\mathbf{R}_1}^y &= L_{\mathbf{R}_3}^y = \frac{i}{2}(b^\dagger - b + c^\dagger - c), & L_{\mathbf{R}_2}^y &= L_{\mathbf{R}_4}^y = -\frac{i}{2}(b^\dagger - b + c - c^\dagger), \\ L_{\mathbf{R}_1}^z &= -L_{\mathbf{R}_3}^z = -\frac{\sin\theta}{2}(b + b^\dagger + c + c^\dagger), & L_{\mathbf{R}_2}^z &= -L_{\mathbf{R}_4}^z = \frac{\sin\theta}{2}(b + b^\dagger - c - c^\dagger). \end{aligned}$$

Note that only HP boson operator $b^\dagger$ and $c^\dagger$ appear in the above equation and there is no $d^\dagger$. This is consistent with the fact that the local loop current is approximated by spin 1 object. Since $d^\dagger$ flips S^z by 2, it does not couple to neutron scattering. We can introduce symmetric and anti-symmetric combinations $a_1 = (b + c)/\sqrt{2}$ and $a_2 = (b - c)/\sqrt{2}$ to simplify above equations. The highest energy mode is a mixture of $a_1^\dagger$ and $d^\dagger$, therefore the highest energy mode should still be observable in principle by neutron scattering with reduced amplitude through exciting $a_1^\dagger$ bosons.

For notational simplicity, we introduce the following quantity.

$$C^{\mu\nu} = \sum_{a,b} e^{i\mathbf{q} \cdot (\mathbf{R}_a - \mathbf{R}_b)} \int_{-\infty}^{\infty} \langle L_{-\mathbf{q},a}^\mu(0) L_{\mathbf{q},b}^\nu(t) \rangle e^{-i\omega t} dt \quad (\text{D2})$$

Then the cross-section can be written as

$$\begin{aligned} \frac{d^2\sigma}{d\Omega dE'} &= \frac{k'}{k} \left[(1 - \hat{q}_x^2) C^{xx} + (1 - \hat{q}_y^2) C^{yy} + (1 - \hat{q}_z^2) C^{zz} \right. \\ &\quad \left. - \hat{q}_x \hat{q}_y (C^{xy} + C^{yx}) - \hat{q}_y \hat{q}_z (C^{yz} + C^{zy}) - \hat{q}_x \hat{q}_z (C^{zx} + C^{xz}) \right] \quad (\text{D3}) \end{aligned}$$

We find the diagonal elements of $C^{\mu\nu}$ as follows,

$$\begin{aligned}
C^{xx} &= 2 \cos^2 \theta (\sin \mathbf{q} \cdot \mathbf{R}_1 + \sin \mathbf{q} \cdot \mathbf{R}_2)^2 \\
&\times \int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle + \langle a_1^\dagger(0) a_1(t) \rangle + \langle a_1(0) a_1^\dagger(t) \rangle + \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt \\
C^{yy} &= 2 \cos^2 \mathbf{q} \cdot \mathbf{R}_1 \int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle - \langle a_1^\dagger(0) a_1(t) \rangle - \langle a_1(0) a_1^\dagger(t) \rangle + \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt \\
&+ 2 \cos^2 \mathbf{q} \cdot \mathbf{R}_2 \int_{-\infty}^{\infty} \left[\langle a_2(0) a_2(t) \rangle - \langle a_2^\dagger(0) a_2(t) \rangle - \langle a_2(0) a_2^\dagger(t) \rangle + \langle a_2^\dagger(0) a_2^\dagger(t) \rangle \right] e^{-i\omega t} dt \\
C^{zz} &= 2 \sin^2 \theta \left(\sin^2 \mathbf{q} \cdot \mathbf{R}_1 \int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle + \langle a_1^\dagger(0) a_1(t) \rangle + \langle a_1(0) a_1^\dagger(t) \rangle + \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt \right. \\
&\left. + \sin^2 \mathbf{q} \cdot \mathbf{R}_2 \int_{-\infty}^{\infty} \left[\langle a_2(0) a_2(t) \rangle + \langle a_2^\dagger(0) a_2(t) \rangle + \langle a_2(0) a_2^\dagger(t) \rangle + \langle a_2^\dagger(0) a_2^\dagger(t) \rangle \right] e^{-i\omega t} dt \right) \tag{D4}
\end{aligned}$$

Here we have made use of the fact that $\langle a_1 a_2 \rangle = \langle a_1^\dagger a_2 \rangle = \langle a_1 a_2^\dagger \rangle = \langle a_1^\dagger a_2^\dagger \rangle = 0$.

For the off-diagonal elements, we find that

$$\begin{aligned}
C^{xy} &\propto \int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle + \langle a_1^\dagger(0) a_1(t) \rangle - \langle a_1(0) a_1^\dagger(t) \rangle - \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt \\
C^{yx} &\propto \int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle - \langle a_1^\dagger(0) a_1(t) \rangle + \langle a_1(0) a_1^\dagger(t) \rangle - \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt
\end{aligned}$$

The cross term of above two equations cancels out. In Eq (D8), we show that $\langle a_1 a_1 \rangle = \langle a_1^\dagger a_1^\dagger \rangle$ and $\langle a_2 a_2 \rangle = \langle a_2^\dagger a_2^\dagger \rangle$. Because of this identity, the square terms also cancels out, thus we have $C^{xy} + C^{yx} = 0$.

Similarly we find that

$$\begin{aligned}
C^{zy,yz} &\propto \left(\int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle \pm \langle a_1^\dagger(0) a_1(t) \rangle \mp \langle a_1(0) a_1^\dagger(t) \rangle - \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt \right. \\
&\left. + \int_{-\infty}^{\infty} \left[\langle a_2(0) a_2(t) \rangle \pm \langle a_2^\dagger(0) a_2(t) \rangle \mp \langle a_2(0) a_2^\dagger(t) \rangle - \langle a_2^\dagger(0) a_2^\dagger(t) \rangle \right] e^{-i\omega t} dt \right)
\end{aligned}$$

Due to the same reason, we have $C^{zy} + C^{yz} = 0$. Then the only non-zero off-diagonal term is

$$\begin{aligned}
C^{xz} &= C^{zx} = 2 \sin \theta \cos \theta (\sin \mathbf{q} \cdot \mathbf{R}_1 + \sin \mathbf{q} \cdot \mathbf{R}_2) \sin(\mathbf{q} \cdot \mathbf{R}_1) \\
&\times \int_{-\infty}^{\infty} \left[\langle a_1(0) a_1(t) \rangle + \langle a_1^\dagger(0) a_1(t) \rangle + \langle a_1(0) a_1^\dagger(t) \rangle + \langle a_1^\dagger(0) a_1^\dagger(t) \rangle \right] e^{-i\omega t} dt \tag{D5}
\end{aligned}$$

The HP boson can be expressed in terms of Bogoliubov bosons as follows

$$a_1 = u_1 \alpha + v_1 \alpha^\dagger + u_3 \gamma + v_3 \gamma^\dagger \tag{D6}$$

$$a_2 = u_2 \beta + v_2 \beta^\dagger \tag{D7}$$

with momentum dependent coefficient u_i and v_i for $i = 1, 2, 3$. Here $\alpha^\dagger$, $\beta^\dagger$ and $\gamma^\dagger$ are the creation operators of the

three collective modes. At $T = 0$, we find the following correlation functions

$$\begin{aligned}
\int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_1(0) a_1(t) \rangle &= \int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_1^\dagger(0) a_1^\dagger(t) \rangle = u_1 v_1 \delta(\omega - \omega_1(\mathbf{q})) + u_3 v_3 \delta(\omega - \omega_3(\mathbf{q})) \\
\int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_1(0) a_1^\dagger(t) \rangle &= u_1^2 \delta(\omega - \omega_1(\mathbf{q})) + u_3^2 \delta(\omega - \omega_3(\mathbf{q})) \\
\int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_1^\dagger(0) a_1(t) \rangle &= v_1^2 \delta(\omega - \omega_1(\mathbf{q})) + v_3^2 \delta(\omega - \omega_3(\mathbf{q})) \\
\int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_2(0) a_2(t) \rangle &= \int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_2^\dagger(0) a_2^\dagger(t) \rangle = u_2 v_2 \delta(\omega - \omega_2(\mathbf{q})) \\
\int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_2(0) a_2^\dagger(t) \rangle &= u_2^2 \delta(\omega - \omega_2(\mathbf{q})) \\
\int_{-\infty}^{\infty} e^{-i\omega t} dt \langle a_2^\dagger(0) a_2(t) \rangle &= v_2^2 \delta(\omega - \omega_2(\mathbf{q}))
\end{aligned} \tag{D8}$$

Since we ignored the damping effect, there are only delta function like peaks. Note all 3 collective mode dispersions appear in the above correlation functions. Collecting all results, we find

$$\begin{aligned}
\frac{d^2 \sigma}{d\Omega dE'} &= \frac{k'}{k} \left(\left[4(1 - \hat{q}_x^2) F_{xx} + (1 - \hat{q}_z^2) F_{zz1} - \hat{q}_x \hat{q}_z F_{xz} \right] \right. \\
&\quad \times \left[(u_1 + v_1)^2 \delta(\omega - \omega_1(\mathbf{q})) + (u_3 + v_3)^2 \delta(\omega - \omega_3(\mathbf{q})) \right] \\
&\quad + (1 - \hat{q}_y^2) F_{yy1} \left[(u_1 - v_1)^2 \delta(\omega - \omega_1(\mathbf{q})) + (u_3 - v_3)^2 \delta(\omega - \omega_3(\mathbf{q})) \right] \\
&\quad \left. + [(1 - \hat{q}_y^2) F_{yy2} (u_2 - v_2)^2 + (1 - \hat{q}_z^2) F_{zz2} (u_2 - v_2)^2] \delta(\omega - \omega_2(\mathbf{q})) \right)
\end{aligned} \tag{D9}$$

with $F_{xx} = 2 \cos^2 \theta (\sin \mathbf{q} \cdot \mathbf{R}_1 + \sin \mathbf{q} \cdot \mathbf{R}_2)^2$, $F_{yy1} = 2 \cos^2(\mathbf{q} \cdot \mathbf{R}_1)$, $F_{yy2} = 2 \cos^2(\mathbf{q} \cdot \mathbf{R}_2)$, $F_{zz1} = 2 \sin^2 \theta \sin^2(\mathbf{q} \cdot \mathbf{R}_1)$, $F_{zz2} = 2 \sin^2 \theta \sin^2(\mathbf{q} \cdot \mathbf{R}_2)$ and $F_{xz} = 2 \sin \theta \cos \theta (\sin \mathbf{q} \cdot \mathbf{R}_1 + \sin \mathbf{q} \cdot \mathbf{R}_2) \sin(\mathbf{q} \cdot \mathbf{R}_1)$.

- ²⁵ Actually, since the interactions between $\mathbf{L}$ at different sites are due to currents and not exchange, the model should have two parameters J_{21} and J_{22} with the following restriction: The symmetry of the problem requires that the interactions among the σ operators for two sites in the (x, y) -direction with respect to each other equals the interaction between the τ operators in the (y, x) directions²⁹. We have ignored this subtlety below by taking $J_1 = J_2 = J_{21} = J_{22}$ for most of the calculations in the paper.
